6.4.27 Advice June 2013

ECOREGION North Sea STOCK Sole in Subarea IV (North Sea)

Advice for 2014

ICES advises on the basis of stage one the EU management plan (Council Regulation No. 676/2007) that landings in 2014 should be no more than 11 900 tonnes. Discards are known to take place but cannot be quantified, therefore total catches cannot be calculated.

Figure 6.4.27.1 Sole in Subarea IV (North Sea). Summary of stock assessment (weights in thousand tonnes). Top right: SSB and F for the time series used in the assessment.

SSB has fluctuated around the precautionary reference points for the last decade and is estimated to be well above B_{pa} in 2013. Fishing mortality has shown a declining trend since 1995 and is estimated to be close to Fmsy in 2012.

Management plans

There is a two-stage management plan for North Sea sole and plaice (Council Regulation (EC) No. <u>676/2007</u>, see Annex 6.4.27). An evaluation of the plan (ICES, 2010) concluded that the management plan is precautionary. The stocks are presently in stage two of the plan; implementation of this second stage (as stipulated in article 5 of the EC regulation) is not yet defined.

Biology

Sole is a long lived flatfish species and can reach an age of over 40 years. Sole is a nocturnal predator and therefore more susceptible to capture by fisheries at night than in daylight. The North Sea is the most northern border of the distribution of this species. In cold winters it withdraws to the deeper, warmer waters of the Southern North Sea. The main spawning takes place in the second quarter in coastal areas close to the nurseries. The main diet of sole consists of worms and small soft-shelled bivalves. The large fluctuation in the stock are caused by exceptional strong year classes, which occasionally occur.

Environmental influence on the fish

Large mortality of adult fish has been observed in extremely cold winters (1963) if the water temperature drops below 3 degrees.

The fisheries

Sole is mainly caught by the beam-trawl fleet working with 80 mm mesh mixed with other species. An increasing proportion of the traditional beam trawl fleet is switching to sumwing and/or pulse trawl. Other directed fisheries for sole are carried out with gill nets and otter trawls. Bycatches of sole in other fisheries are small.

Catch distribution Total catches are unknown. Landings (2012) = 11.6 kt, 83.8% beam trawl, 13.6% gill / trammel nets, 2.2% otter trawl, 0.4% other). Total discards estimates are not available

Effects of the fisheries on the ecosystem

The mixed plaice and sole fishery is dominated by bottom trawls, with bycatch of both commercial and non-commercial species and a physical impact on the seabed. Bottom trawling impacts biomass, production, and species richness. Trawling impact differs among benthic habitats and is likely to be more important in deeper water with silty sediments than in shallow areas characterized by sandy grounds. Days-at-sea regulations, high oil prices, and changes in the ratio of TACs for plaice and sole have led to a transfer of fishing effort to the southern North Sea where sole and juvenile plaice tend to be more abundant, leading to an increase in discarding of small plaice in the beginning of the 2000s.

Quality considerations

There are divergent signals between the scientific survey and the commercial data used to tune the sole assessment. A survey covering the whole area would be a more suitable index of abundance. The commercial data used to tune the assessment may be biased due to gradual changes in gear composition, with different catchability, used in this fishery (puls trawl, sum wing). Data on the type of gear used is needed in logbooks. Discard are not included in the assessment as time series are not available yet.

Mixed fisheries assumptions

- A. Maximum scenario: Fleets stop fishing when last quota exhausted
- B. Minimum scenario: Fleets stop fishing when first quota exhausted
- C. Cod management plan scenario: Fleets stop fishing when cod quota exhausted
- D. SQ effort scenario: Effort in 2013 and 2014 as in 2012
- E. Effort management scenario: Effort reductions according to cod and flatfish management plans

Management plan

Both the North Sea plaice and sole stocks have been within safe biological limits in the last two years. According to the management plan (Article 3.2), this signals the end of stage one. Application of the plan is on the basis of transitional arrangements until an evaluation of the plan has been conducted (as stipulated in article 5 of the EC regulation).

Following the EU multiannual plan stage 1 (as rules relating to the setting of F for stage 2 are not yet defined) would imply a 10% reduction of F to 0.21, which results in a TAC (landings) reduction of more than 15%. Therefore, the maximum TAC reduction of 15% is applied, resulting in landings of no more than 11 900 t in 2014. This is expected to

¹⁾ SSB 2015 relative to SSB 2014.

²⁾ Human Consumption landings 2014 relative to TAC 2013.

lead to an SSB of 46 070 t in 2015. Discards are known to take place but cannot be quantified, therefore total catches cannot be calculated.

ICES has evaluated the plan and considers it to be precautionary (ICES, 2010).

MSY approach

Following the ICES MSY approach implies fishing mortality to be reduced to 0.22 (F_{MSY} , as SSB 2012 > MSY $B_{trigger}$), resulting in landings of 11 194 t in 2014. Discards are known to take place but cannot be quantified, therefore total catches cannot be calculated. This is expected to lead to an SSB of 46 916 t in 2015.

Given that the current (2012) estimate of fishing mortality is close to FMSY there is no need to follow a transition scheme towards this reference value.

Precautionary approach

The F_{pa} for North Sea sole is 0.4. This would lead to landings of 18 540 t in 2014 and an SSB of 39 175 t in 2015. Discards are known to take place but cannot be quantified, therefore total catches cannot be calculated.

Mixed fisheries

In contrast to single-species advice there is no single recommendation for mixed fisheries (ICES, 2013b), but rather a range of example scenarios, assuming fishing patterns and catchability in 2013 and 2014 are unchanged from those in 2012. Major differences between the outcomes of the various scenarios indicate potential undershoot or overshoot of the advised landings corresponding to the single-species advice. As a result, fleet dynamics may change, but cannot be determined.

Cod is the limiting species for the North Sea and eastern channel demersal fisheries in 2014. Following the 'cod' scenario (full implementation of the cod management plan), the sole management plan catch options could not be fully utilised.

Additional considerations

Sole are mainly caught in a mixed beam-trawl fishery with plaice and other flatfish using 80 mm mesh in the southern North Sea. The minimum mesh size in the mixed beam-trawl fishery in the southern North Sea means that large numbers of undersized plaice are discarded. There are indications that in recent years sole discarding has increased. Reasons for the increase are unclear and should be investigated. Measures to reduce discarding in the mixed beam-trawl fishery would greatly benefit these stocks. An increase in the minimum landing size of sole could provide an incentive to fish with larger mesh sizes and would therefore mean a reduction in the discarding of plaice. The minimum landing size of North Sea sole is 24 cm. An increased mesh size in the fishery would reduce the catch of undersized plaice, but would also result in a loss of marketable sole.

The peaks in the historical time-series of SSB of North Sea sole correspond with the occasional occurrence of strong year classes. Due to a high fishing mortality the SSB has declined during the nineties. The SSB and landings have in recent years been dominated by the 2005 year class. The effect of the 2005 year class is now, however, starting to decline. The 2009 year class, which entered into the SSB in 2012, is above average.

The decline in the fishing mortality starting in the mid-2000s coincides with a reduction of capacity in the beam-trawl fleet. High fuel prices may have contributed to the decrease in effort and, consequently, of fishing mortality.

The assumption of status quo fishing mortality in 2013 in the forecast indicates that the TAC for 2013 will not be taken. The TAC for sole has not been fully utilized in 2010, 2011 and 2012, and in the last 3 years effort limitations have not been restrictive.

ICES has developed a generic approach to evaluate whether new survey information that becomes available in September forms a basis to update the advice. If this is the case, ICES will publish new advice in November 2013.

Impacts of fisheries on the ecosystems

Currently the mixed sole and plaice fishery is dominated by bottom trawls, with bycatch of both commercial and non-commercial species and a physical impact on the seabed. Bottom trawling can impact biomass, production, and species richness. For the North Sea, an ecosystem model showed that the bottom-trawl fleet reduced benthic biomass and

production by 56% and 21%, respectively, compared with an un-fished situation (Hiddink *et al.*, 2006; Hinz *et al.*, 2008). The impact of fishing since then has probably reduced by considerable reduction in effort and a change to different gears. Continuous fishing has caused a shift from communities dominated by relatively sessile, emergent, and high biomass species to communities dominated by infaunal, smaller-bodied fauna (Kaiser *et al.*, 2000). Within species, the size selectivity may lead to a shift in the age and size at maturation. For example, in recent years plaice and sole have become mature at younger ages and at smaller sizes than in the past.

Management plan

A multiannual plan for plaice and sole in the North Sea was adopted by the EU Council in 2007 (EC regulation 676/2007) which describes two stages: a recovery plan during its first stage and a management plan during its second stage. Objectives are defined for these two stages, rebuilding the stocks to within safe biological limits in the first and exploiting the stocks at MSY in the second. Stage 1 is deemed to be completed when both stocks have been within safe biological limits for two consecutive years. TAC-setting procedures are provided to accommodate stage 1 as well as a transitional period during which an impact assessment and evaluation should take place to reconsider long-term objectives. The plaice stock has been within safe biological limits as defined by the plan since 2005. The sole stock has been within safe biological limits in terms of fishing mortality since 2008. The 2012 and 2013 estimates are well above B_{pa} (43 kt and 39 kt). Consequently, ICES concludes that the objectives of stage 1 are currently met and provides advice based on the plan's TAC-setting procedure, acknowledging the stock to be in a transitional stage at present.

The current plan prescribes effort limitations (kW-days per metier) to be adjusted in line with changes in fishing mortality. The current advice implies a reduction of 10% in effort (following a 10% reduction in F to 0.21 for sole) as well as an increase in fishing mortality for plaice.

In 2012, ICES evaluated a proposal by the Netherlands for an amended management plan, which could serve as the 'stage 2' plan (Coers *et al.* 2012). The amendments included changing the target F for sole to 0.25 and to cease reductions of effort. ICES concluded that the plan – subject to those amendments –is consistent with the precautionary approach and the principle of maximum sustainable yield (ICES, 2012b). However, implementation of stage two of the plan is not yet defined.

Regulations and their effects

Regulated effort restrictions in the EU were introduced in 2003 (annexes to the annual TAC regulations) for the protection of the North Sea cod stock. In addition, a long-term plan for the recovery of cod stocks was adopted in 2008 (EC regulation 1342/2008). In 2009, the effort management programme switched from a days-at-sea to a kW-day system (EC regulation 43/2009), in which different amounts of kW-days are allocated within each area by member state to different groups of vessels depending on gear and mesh size. A minor part of the fleets exploiting sole, i.e. otter trawls (OTB) with a mesh size equal to or larger than 100 mm included in TR1, have since 2009 been affected by the regulation. The beam trawl fleet (BT2) was affected by this regulation only once in 2009 but not afterwards.

The current sole and plaice long-term management plan (Council Regulation (EC) No. 676/2007) also specifically reduces effort as a management measure, affecting BT2 and occasionally trammelnet (GT1) gears since the implementation of the plan. Effort ceilings are updated annually. However, for 2013, the European Council decided upon a roll-over of effort level of 2012 into 2013 for both the cod and the sole/plaice management plans.

Overall nominal effort (kW-days) by EU demersal trawls, seines, beam trawls, gill- and trammelnets, and longlines (all mesh sizes included) in the North Sea, Skagerrak, and Eastern Channel has been substantially reduced since the implementation of the two successive effort management plans in 2003 and 2008 (−40% between 2003 and 2012, −16% between 2008 and 2012). Effort by the beam trawl fleet in small mesh size (80–120 mm, BT2) has shown a sharp decline (−45% between 2003 and 2012), while effort in large mesh size (≥120 mm, BT1) has increased significantly in 2012 after a decade of continuous decline.

Changes in fishing technology and fishing patterns

The combination of days-at-sea regulations, high oil prices, and the constrained TAC for plaice (due to the 15% limitation in the multiannual plan) and the relatively stable TAC for sole have lead to a more southern fishing pattern in the North Sea, where sole has become relatively more abundant. This concentration of fishing effort in the South has resulted in increased discarding of juvenile plaice that are mainly distributed in those areas. This process could be aggravated by the movement of juvenile plaice to deeper waters in recent years where they become more susceptible to the fishery. Lpue data also show a slower recovery of stock size in the southern regions that may be caused by higher fishing effort in the more coastal regions.

The increased use of "SumWing" and electric "Pulse trawls" will increasingly affect catchability and selectivity of North Sea sole. In 2011, approximately 30 derogation licenses for Pulse trawls were taken into operation, which increased to 42 in 2012. Debate is ongoing in the EU about extensions of an additional 42 derogation licenses as well as possible amendments to EU regulations which would permanently legalize the use of pulse gears. ICES concluded that pulse trawls experienced reduced catch rates (kg/hr) of undersized sole, compared to standard beam trawls (ICES, 2006). Catch rates of sole above the minimum landings size from research vessel trials were higher but the commercial feasibility study suggested lower catch rates. The introduction of innovative gears may lead to changes in how the ecosystem is impacted by the plaice and sole targeting fleet. Because of the lighter gear and lower towing speed, pulse vessels generate a lower swept-area per hour and reduced bycatch of benthic organisms. The new gears may change fishing patterns as well.

ICES responded to a request by France on the use of the Pulse trawl (ICES, 2012a) and concluded that the introduction of electric pulse systems could significantly reduce fishing mortality of target and non-target species, including benthic organisms, assuming there is no corresponding increase in unaccounted (avoidance) mortality. However, not all relevant issues (such as delayed mortality and long-term population effects) have been fully studied and ICES therefore considers that the available data are insufficient to recommend the large-scale use of the electric pulse trawl in fisheries.

The introduction of a new mesh meter (the Omega meter) in 2010 has lead to a slight increase in the effective mesh size in the fishery.

Information from the fishing industry

The Fishers' North Sea stock survey again took place in 2012 (Napier, 2012; Figure 6.4.27.4). Overall, about one-third of respondents (35%) reported that sole were 'more' abundant in 2012, a higher proportion than 2011 (24%). Most fishermen had the perception that the recruitment was "Moderate" (53%). The overall perceptions of the fishing industry reflect a more positive impression of the trends in the sole stock than estimated by ICES.

Preliminary observations by the industry using "Pulse trawls" in 2011 show higher catch rates of sole than traditional beam trawls.

Uncertainties in the assessment and forecast

Estimations of sole stock status appear to have a slight retrospective under-estimation of fishing mortality and over-estimation of SSB, which have resulted in forecast bias.

Changes in commercial fleets (e.g. from beam to pulse trawls) used for tuning the assessment may have introduced bias.

The SNS survey in 2012 was conducted two weeks later and with a different vessel (Tridens) than usual (ISIS), because the ISIS was unavailable due to technical problems. The 2012 SNS datapoint was also the lowest in the timeseries and was not consistent with the BTS survey for all ages. An exploratory analysis was done with additional data from a German survey in the German bight. This survey also showed different trends than the BTS, and was more consistent with the SNS. Therefore it was concluded that the SNS datapoint should be kept in the analysis.

Comparison of previous assessment and advice

The 2013 assessment is in very close agreement with that of 2012. As last year, the advice is based on the EU management plan.

Annex 6.4.27

Extract from Council Regulation (EC) No 676/2007 of 11 June 2007 establishing a multiannual plan for fisheries exploiting stocks of plaice and sole in the North Sea

Article 2 Safe biological limits

- 1. For the purposes of this Regulation, the stocks of plaice and sole shall be deemed to be within safe biological limits in those years in which, according to the opinion of the Scientific, Technical, and Economic Committee for Fisheries (STECF), all of the following conditions are fulfilled:
 - (a) the spawning biomass of the stock of plaice exceeds 230 000 tonnes;
 - (b) the average fishing mortality rate on ages two to six years experienced by the stock of plaice is less than 0,6 per year;
 - (c) the spawning biomass of the stock of sole exceeds 35 000 tonnes;
 - (d) the average fishing mortality rate on ages two to six years experienced by the stock of sole is less than 0,4 per year.
- 2. If the STECF advises that other levels of biomass and fishing mortality should be used to define safe biological limits, the Commission shall propose to amend paragraph 1

Article 3 Objectives of the multiannual plan in the first stage

- 1. The multiannual plan shall, in its first stage, ensure the return of the stocks of plaice and of sole to within safe biological limits.
- 2. The objective specified in paragraph 1 shall be attained by reducing the fishing mortality rate on plaice and sole by 10 % each year, with a maximum TAC variation of 15 % per year until safe biological limits are reached for both stocks.

Article 4 Objectives of the multiannual plan in the second stage

- 1. The multiannual plan shall, in its second stage, ensure the exploitation of the stocks of plaice and sole on the basis of maximum sustainable yield.
- 2. The objective specified in paragraph 1 shall be attained while maintaining the fishing mortality on plaice at a rate equal to or no lower than 0,3 on ages two to six years.
- 3. The objective specified in paragraph 1 shall be attained while maintaining the fishing mortality on sole at a rate equal to or no lower than 0,2 on ages two to six years.

Article 5 Transitional arrangements

1. When the stocks of plaice and sole have been found for two years in succession to have returned to within safe biological limits the Council shall decide on the basis of a proposal from the Commission on the amendment of Articles 4(2) and 4(3) and the amendment of Articles 7, 8 and 9 that will, in the light of the latest scientific advice from the STECF, permit the exploitation of the stocks at a fishing mortality rate compatible with maximum sustainable yield.

Article 8 Procedure for setting the TAC for sole:

- 1) The Council shall adopt a TAC for sole at that level of catches which, according to a scientific evaluation carried out by STECF is the higher of:
 - a) that TAC the application of which will result in the level of fishing mortality rate of 0,2 on ages two to six years in its year of application;
 - b) that TAC the application of which will result in a 10 % reduction in the fishing mortality rate in its year of application compared to the fishing mortality rate estimated for the preceding year.
- 2) Where the application of paragraph 1 would result in a TAC which exceeds the TAC of the preceding year by more than 15 %, the Council shall adopt a TAC which is 15 % greater than the TAC of that year.
- 3) Where the application of paragraph 1 would result in a TAC which is more than 15 % less than the TAC of the preceding year, the Council shall adopt a TAC which is 15 % less than the TAC of that year.
